PROBLEM 1

Let M be a complete Riemannian manifold with non-positive sectional curvature. Prove that

$$|(d\exp_p)_v(w)| \ge |w|$$

for all $p \in M$, $v \in T_pM$, and $w \in T_v(T_pM)$.

Proof. We compare M to Euclidean space \mathbb{R}^n , noting that $K = K_M \leq \tilde{K} = K_{\mathbb{R}^n} = 0$. Now, let $\gamma(t) = \exp_p(tv)$ be the geodesic generated by v in M, and observe that

$$(d\exp_p)_{tv}(tw)$$

is a Jacobi field along γ (in fact, this is the first Jacobi field Do Carmo studies in chapter 5). Since M is complete, such a field is defined, as $\exp_n(tv)$ is defined.

Now, in \mathbb{R}^n , we construct $\tilde{\gamma}(t) = \exp_0(tv) = tv$ and note that

$$\tilde{J}(t) = (d \exp_0)_{tv}(tw) = tw$$

Now, clearly

$$\|\gamma'(t)\| = \|\tilde{\gamma}'(t)\| = v$$

and

$$J(0) = \tilde{J}(0) = 0$$

and

$$g(J'(0), \gamma'(0)) = g(\tilde{J}'(0), \tilde{\gamma}'(0)) = g(w, v)$$

and

$$||J'(0)|| = ||\tilde{J}'(0)|| = ||w||$$

and since M has non-positive sectional curvature, γ has no conjugate points. Thus, the hypotheses for the Rauch comparison theorem are satisfied, and immediately we know that

$$|\tilde{J}(t)| \le |J(t)|$$

plugging in t = 1, we observe that

$$|(d\exp_p)_v(w)| \ge |w|$$

as desired. $\hfill\Box$

PROBLEM 2

Let

$$f''(t) + K(t)f(t) = 0, f(0) = 0, t \in [0, \ell]$$

$$\tilde{f}''(t) + \tilde{K}(t)\tilde{f}(t) = 0, \tilde{f}(0) = 0, t \in [0, \ell]$$

be two ODEs. Suppose $\tilde{K}(t) \geq K(t)$ for $t \in [0, \ell]$ and that $f'(0) = \tilde{f}'(0) = 1$.

Part a

Show that for all $t \in [0, \ell]$,

$$0 = \int_0^t \left\{ \tilde{f}(f'' + Kf) - f(\tilde{f}'' + \tilde{K}\tilde{f}) \right\} dt$$
$$= \left[\tilde{f}f' - f\tilde{f}' \right]_0^t + \int_0^t (K - \tilde{K})f\tilde{f}dt$$

and conclude that the first zero of f does not occur before the first zero of \tilde{f} .

Proof. The first equality follows immediately from the differential equation. That is,

$$\int_0^t \left\{ \tilde{f}(f'' + Kf) - f(\tilde{f}'' + \tilde{K}\tilde{f}) \right\} dt = \int_0^t \tilde{f}(0) - f(0)dt = 0$$

for the second equality, we integrate by parts. Noticing that

$$\int_0^t \tilde{f}f''dt = [\tilde{f}f']_0^t - \int_0^t \tilde{f}'f'dt$$

we see that

$$\int_{0}^{t} \left\{ \tilde{f}(f'' + Kf) - f(\tilde{f}'' + \tilde{K}\tilde{f}) \right\} dt$$

$$= \int_{0}^{t} \tilde{f}f'' dt - \int_{0}^{t} f\tilde{f}'' dt + \int_{0}^{t} K\tilde{f}f dt - \int_{0}^{t} \tilde{K}\tilde{f}f dt$$

$$= [\tilde{f}f']_{0}^{t} - \int_{0}^{t} \tilde{f}'f' dt - [f\tilde{f}']_{0}^{t} + \int_{0}^{t} \tilde{f}'f' dt + \int_{0}^{t} (K - \tilde{K})f\tilde{f}dt$$

$$= [\tilde{f}f' - f\tilde{f}']_{0}^{t} + \int_{0}^{t} (K - \tilde{K})f\tilde{f}dt$$

as desired.

Now, we know that f(t) > 0 on a neighborhood of zero. Let t_0 be the first zero of \tilde{f} (so $\tilde{f}(t) > 0$ for $t < t_0$). Assume for contradiction that for some $t_1 < t_0$, $f(t_1) = 0$. Furthermore, suppose this is the first zero (that is f(t) > 0 for $t < t_1$). Then, $f'(t_1) < 0$, $\tilde{f}(t_1) > 0$, and so

$$\left[\tilde{f}f' - f\tilde{f}'\right]_0^{t_1} + \int_0^{t_1} (K - \tilde{K})f\tilde{f}dt = \tilde{f}(t_1)f'(t_1) - f(t_1)\tilde{f}'(t_1) + \int_0^{t_1} (K - \tilde{K}f\tilde{f}dt) dt$$
$$= \tilde{f}(t_1)f'(t_1) + \int_0^{t_1} (K - \tilde{K}f\tilde{f}dt) dt$$

now $\tilde{f}(t_1) > 0$, $f'(t_1) < 0$, $(K - \tilde{K}) < 0$ and $f(t)\tilde{f}(t) > 0$ for $t < t_1$. Thus,

$$\tilde{f}(t_1)f'(t_1) + \int_0^{t_1} (K - \tilde{K}f\tilde{f}dt < 0)$$

a contradiction.

Part b

Suppose $\tilde{f}(t) > 0$ on $(0, \ell]$. Show that $f(t) \geq \tilde{f}(t)$ for $t \in [0, \ell]$, and equality holds for $t = t_1$ if and only if $K(t) = \tilde{K}(t)$ on $[0, t_1]$.

Proof. From the first equality in part a, and that $\tilde{f}(t), f(t) > 0$, we see that in order for

$$0 = [\tilde{f}f' - f\tilde{f}']_0^t + \int_0^t (K - \tilde{K})f\tilde{f}dt$$

is satisfied only when

$$[\tilde{f}f' - f\tilde{f}']_0^t = \tilde{f}(t)f'(t) - f(t)\tilde{f}'(t) > 0$$

or,

$$\frac{f'}{f} \ge \frac{\tilde{f}'}{\tilde{f}}$$

In other words,

$$(\log f)' \ge (\log \tilde{f})'$$

Integrating this from t_0 to t, we see that

$$\log f(t) - \log f(t_0) \ge \log \tilde{f}(t) - \log \tilde{f}(t_0)$$

which implies that

$$\frac{f(t)}{\tilde{f}(t)} \ge \frac{f(t_0)}{\tilde{f}(t_0)}$$
